# Higgs Beyond the SM and SUSY

Adam Martin CERN/Notre Dame (adam.martin@cern.ch)

YETI Winter School, IPPP Durham UK, 2013

Wednesday, January 9, 2013

## <u>Outline</u>

#### Lecture #1

- Where are we now and where do we go from here?
- Did it have to be a Higgs?
- EFT for beyond the SM
- Composite Higgs (Higgs as a Goldstone Boson)

#### Lecture #2

- more Composite Higgs (Higgs as a Goldstone Boson)
- where & how to look at LHC

#### Where are we now?

massive W<sup>±</sup>/Z<sup>0</sup> fermions, massless γ, g:
 'electroweak symmetry is broken'

#### Where are we now?

# massive W<sup>±</sup>/Z<sup>0</sup> fermions, massless γ, g: 'electroweak symmetry is broken'

- As of July 4th, 2012...
  - we have a new boson X, with mass ~125 GeV

likely spin-0, likely CP-even

X is observed in channels and with rates similar to what we expect for a SM Higgs boson

#### What now?

• To what extent are EWSB and X related?

Meaning what are the similarities & differences between X and SM Higgs?

• What is the bigger picture?

## Is there a bigger picture?

• LOTS we don't know.. many things we observe are not in the SM.

Dark Matter baryon vs. anti-baryon asymmetry

neutrino masses

# generations, charge assignments

- Scale/properties of these other phenomena is unknown.
- Hope that understanding EWSB ( & connection w/ X boson) will shed some light on these other topics

Was finding a Higgs-like boson inevitable? Is that the only path in nature for what we see?

Was finding a Higgs-like boson inevitable? Is that the only path in nature for what we see?

## NOPE

Was finding a Higgs-like boson inevitable? Is that the only path in nature for what we see?

## NOPE

we know how Higgs works

(see lectures by Mück, Englert, Duehrssen)

$$egin{aligned} H \in (2,1/2) & ext{of SU(2)_w} \otimes ext{U(1)_Y} \ & |D_\mu H|^2 - \lambda (H^\dagger H - rac{v^2}{2})^2 \end{aligned}$$

## Instead lets add a field $\Sigma(\mathbf{x})$ : Pauli matrices $\Sigma(x) = \exp\left(\frac{i 2\pi^a \tau_a}{v}\right) = \mathbf{1}_{2 \times 2} + 2i \frac{\pi_a \tau^a}{v} - 2\frac{\pi_a \pi_b \tau^a \tau^b}{v^2} + \cdots$ 3 "pion" fields EW scale

expanding out, we get a (2x2) matrix

$$\Sigma = \begin{pmatrix} \cos\left(\hat{\pi}/v\right) + i\hat{\pi}_{3}\sin\left(\hat{\pi}/v\right) & i(\hat{\pi}_{1} - i\hat{\pi}_{2})\sin\left(\hat{\pi}/v\right) \\ i(\hat{\pi}_{1} + i\hat{\pi}_{2})\sin\left(\hat{\pi}/v\right) & \cos\left(\hat{\pi}/v\right) - i\hat{\pi}_{3}\sin\left(\hat{\pi}/v\right) \end{pmatrix} \\ \hat{\pi} = \sqrt{\pi_{a}^{2}}, \quad \hat{\pi}_{a} = \pi_{a}/\hat{\pi}$$

remember, the SM Higgs doublet

$$H(x) = \frac{1}{\sqrt{2}} \left( \begin{array}{c} h_1 + i h_2 \\ h_0 + i h_3 \end{array} \right) \quad \begin{array}{l} \text{has 4 fields, our} \\ \Sigma \text{ has 3} \end{array}$$

under SU(2)<sub>w</sub> x U(1)<sub>Y</sub>:  $U_L \Sigma U^{\dagger}_R$ 

$$D_{\mu}\Sigma = \partial_{\mu}\Sigma - ig\vec{W}_{\mu}\Sigma + ig'\Sigma B_{\mu}\tau_{3}$$

how is this different than H? (forget  $U(1)_Y$  for now..)

$$U_L$$
 is a 2 x 2 matrix:  $U_L = \exp(i\alpha_a(x)\tau^a)$ 

acting on the Higgs vs. on  $\Sigma$ :

 $\begin{array}{lll} U_L \ H(x): & \mbox{mixes up the 4 components } h_i \\ & \mbox{ex.} ) \ h_3 \rightarrow h_3 + i \ h_0 \ \alpha_3 - i \ h_1 \ \alpha_1 + i \ h_2 \ \alpha_2 \end{array}$ 

$$U_{L} \Sigma(x)$$
 : shifts the  $\pi_{a}$  fields,  $\pi_{3} \rightarrow \pi_{3} + \alpha_{3}$ 

out of  $\Sigma$ , we have:

$$\mathcal{L}_{\Sigma} = \frac{v^2}{4} \operatorname{tr}(D^{\mu} \Sigma D_{\mu} \Sigma^{\dagger}) + \cdots \quad \text{more derivatives,} \\ \quad \text{etc.}$$

by a gauge transformation:

$$U_L = \Sigma^{\dagger}, \ \Sigma \to \Sigma^{\dagger}\Sigma = \mathbf{1}, \ iD_{\mu}\Sigma = (g \vec{W}_{\mu} - g' B_{\mu})$$

$$\mathcal{L}_{\Sigma} = \frac{v^2}{4} \left( g \, \vec{W}_{\mu} - g' \, B_{\mu} \right)^2 = m_W^2 \, W_{\mu}^+ W^{\mu -} + m_Z^2 \, Z^{\mu} Z_{\mu}$$

so with only 3 degrees of freedom, we can give mass to W<sup>±</sup>/Z (fermions too:  $y_t v Q \Sigma u_R^*$ , etc.). 'Higgsless' EWSB

we haven't explained what dynamics gives  $\Sigma$  ... but no explanation for V(H) in SM.

#### So what's the difference?

Look at  $W_{L} W_{L} \rightarrow W_{L} W_{L}$  scattering in the H &  $\Sigma$  theories (at tree level)

in the SM:

extra contributions coming from Higgs exchange. amplitude  $\rightarrow$  constant  $A \sim \frac{m_H^2}{s}$ 

hW<sup>+</sup>W<sup>-</sup>, etc. couplings set by gauge invariance

#### Unitarity imposes relations on QM amplitudes

tree level amplitude is real, at loop level A gets an imaginary part

<u> $\Sigma$  theory</u>: A ~s/v<sup>2</sup>, Re(A) grows with energy

bigger Re(A) is, bigger Im(A) must get to keep unitary relation.

If Im(A) = Re(A) then 1-loop is same size as tree level = loss of perturbativity = theory is strongly coupled

<u>SM theory:</u> A ~  $m_{H}^2$ , perturbativity retained for all s

#### Unitarity imposes relations on QM amplitudes

tree level amplitude is real, at loop level A gets an imaginary part

<u> $\Sigma$  theory</u>: A ~s/v<sup>2</sup>, Re(A) grows with energy

bigger Re(A) is, bigger Im(A) must get to keep unitary relation.

If Im(A) = Re(A) then 1-loop is same size as tree level = loss of perturbativity = theory is strongly coupled

<u>SM theory:</u> A ~  $m_{H}^2$ , perturbativity retained for all s

#### Unitarity imposes relations on QM amplitudes

tree level amplitude is real, at loop level A gets an imaginary part

<u> $\Sigma$  theory</u>: A ~s/v<sup>2</sup>, Re(A) grows with energy

bigger Re(A) is, bigger Im(A) must get to keep unitary relation.

If Im(A) = Re(A) then 1-loop is same size as tree level = loss of perturbativity = theory is strongly coupled

<u>SM theory:</u> A ~  $m^2_H/s$ , perturbativity retained for all s

we've seen strong coupling before: QCD in the  $\sim 100~\text{MeV} - 1~\text{GeV}$  range

#### in QCD, strong coupling tells us that above a certain energy there is a transition and quarks & gluons are the right degrees of freedom

#### <u>But...</u>

 $\mathcal{L}_{\Sigma}$  has massive particles, but no new scalar state (X, or h) ... so it needs to be augmented

$$\begin{split} \mathcal{L}_{\Sigma} &= \frac{1}{2} (\partial_{\mu} h)^2 + \frac{v^2}{4} \mathrm{tr} (D_{\mu} \Sigma \, D^{\mu} \Sigma^{\dagger}) \left( 1 + \frac{a^2 h}{v} + \frac{b^2}{v^2} + \cdots \right) \\ &- \frac{m_H^2}{2} h^2 + y_{ij} v \, Q_i \, \Sigma \, u_{Rj}^* \left( 1 + \frac{c}{v} \frac{h}{v} + \cdots \right) + \text{h.c.} \end{split}$$

+ analogous terms for other fermions, + terms with more derivatives

Looks familiar?  $a = b = c = 1 \rightarrow SM$  Higgs Lagrangian, where three  $\pi_a$  fields + h combine to the H doublet

but that is just a special case,  $L_{\Sigma}$  is more general: triplet of states eaten by  $W^{\pm}/Z^{0}$  + real scalar = EFT for LHC Higgs

## <u>Higgs EFT</u>

What is the meaning of a, b,  $c \neq 1$ ?

$$A \sim \frac{(s+t)}{v^2} (1-a) + O\left(\frac{m_H^2}{s}\right)$$

for a ≅ 1, energy growth in A is suppressed

pert. lost when  $Re(A) \approx 1/2$ 

partial wave A<sub>I</sub>  $A_0 = \frac{E^2 (1 - a)}{32\pi v^2} = \frac{1}{2} \longrightarrow E_{lim} = \frac{4\sqrt{\pi v}}{\sqrt{1 - a}}$ 

above this scale (& without other terms), strong dynamics

- a=0, strong dynamics ~ TeV scale (Technicolor)
- a=1, theory stays perturbative (SM Higgs)
- $a \approx 1$ , strong dynamics scale pushed higher

#### <u>Higgs EFT</u>

there are processes other than  $W_LW_L \rightarrow W_LW_L$  that can grow with energy

## <u>Higgs EFT</u>

there are existing, indirect constraints on a,b,c

similarly, off-diagonal  $c_{ij}$  strongly constrained by flavor physics diagonal  $c_{ii}$ , b are less constrained

## Higgs EFT in action

several groups (theory & experiment) are already looking at LHC Higgs data in the a,b,c space

#### <u>Recap</u>

- to fit observation, we need massive W<sup>±</sup>/Z<sup>0</sup>/fermions
   + extra scalar
- general setup:  $L_{\Sigma}$  .. contains  $L_{SM}$  in special a = b = c = 1 limit
- for a,b,c $\neq$ 1, L<sub> $\Sigma$ </sub> becomes strongly coupled at some energy E<sub>lim</sub> ... expect (from QCD experience) some new dynamics to enter at that scale
- useful framework for LHC Higgs data
- BUT: What UV dynamics actually leads to L<sub>Σ</sub>? What else (other states, couplings) is present in those scenarios?

## Light scalar fields

 $\frac{m_H^2}{2}h^2$  masses of scalar fields are sensitive to the highest scales of a theory:  $\delta m^2_H \sim \Lambda^2$ 

Having a scalar mass << theory cutoff requires delicate 'unnatural' cancellations = "hierarchy problem". Many BSM scenarios try to address this problem

#### who cares about natural?

#### UK, lead by new player Higgs, defeats Germany in World Cup Final 1000 - 0

theoretically possible, but hard to imagine within the rules we trust... either Higgs is unlike the other particles/players we know, or there is more going on

## Light scalar fields

 $\frac{m_H^2}{2}h^2$  masses of scalar fields are sensitive to the highest scales of a theory:  $\delta m^2_H \sim \Lambda^2$ 

Having a scalar mass << theory cutoff requires delicate 'unnatural' cancellations = "hierarchy problem". Many BSM scenarios try to address this problem

- links scalars to fermions via a symmetry. chiral symmetry protects mass = SUSY (lectures by Slavich)
- shift symmetry:  $h \rightarrow h + c$ , then  $h^2$  forbidden = Higgs as a Goldstone boson

making these symmetries approximate, rather than exact -> light scalar (Higgs)

<u>For starters</u>: let's study a simpler setup, 2 flavor QCD. As we'll see, the pion of QCD is a pNGB, so many lessons from  $L_{\pi}$  will carry over to LH.

At high energy, QCD is quarks and gluons

 $\mathcal{L} = i\bar{u}_L \mathcal{D} u_L + i\bar{d}_L \mathcal{D} d_L + i\bar{u}_R \mathcal{D} u_R + i\bar{d}_R \mathcal{D} d_R$ 

this theory is invariant under rotations of LH, RH quarks among themselves

$$\left(\begin{array}{c}u_L'\\d_L'\end{array}\right) = U_L \left(\begin{array}{c}u_L\\d_L\end{array}\right) \qquad \qquad \left(\begin{array}{c}u_R'\\d_L'\end{array}\right) = U_R \left(\begin{array}{c}u_R\\d_R\end{array}\right)$$

global symmetry is  $SU(2)_L \otimes SU(2)_R$ 

at E ~ 1 GeV, the strong force becomes confining, quarks & antiquarks get bound together.. only color singlet states allowed

color-singlet condensates form:  $\langle \bar{Q}_L Q_R \rangle \neq 0$ 

under global symmetry:  $\langle \bar{Q}_L Q_R \rangle \rightarrow \langle \bar{Q}_L U_L^{\dagger} U_R Q_R \rangle$ 

only invariant when  $U_L = U_R$ , the 'vectorial' subgroup

so, as a result of the strong dynamics, symmetry has been broken:  $SU(2)_{L} \otimes SU(2)_{R} \rightarrow SU(2)_{V}$ 

Goldstone's theorem: for each generator of a spontaneously broken, continuous, global symmetry → a massless scalar (a Goldstone boson)

at E ~ 1 GeV, the strong force becomes confining, quarks & antiquarks get bound together.. only color singlet states allowed

color-singlet condensates form:  $\langle \bar{Q}_L Q_R \rangle \neq 0$ 

under global symmetry:  $\langle \bar{Q}_L Q_R \rangle \rightarrow \langle \bar{Q}_L U_L^{\dagger} U_R Q_R \rangle$ 

only invariant when  $U_L = U_R$ , the 'vectorial' subgroup

so, as a result of the strong dynamics, symmetry has been broken:  $SU(2)_L \otimes SU(2)_R \rightarrow SU(2)_V + 3 \text{ NGB}$ 

Goldstone's theorem: for each generator of a spontaneously broken, continuous, global symmetry → a massless scalar (a Goldstone boson)

the interactions of the NGB can be described by the 'chiral lagrangian'

introduce: 
$$U = \exp\left(\frac{2i\vec{\pi}}{f_{\pi}}\right)$$
  $\vec{\pi} = \pi_a \tau_a$   
pion decay constant = 93 MeV

fix  $U \rightarrow U_L \cup U_R^{\dagger}$  then **U** has the same transformation properties as  $\langle Q_L \overline{Q}_R \rangle$ 

 $UU^{\dagger} = 1$ , so terms in  $L_{\pi}$  must involve derivatives

$$\mathcal{L}_{\pi} = \frac{f_{\pi}^2}{4} \operatorname{tr}(\partial_{\mu} U \,\partial^{\mu} U^{\dagger}) + c_1 \operatorname{tr}(\partial_{\mu} U \,\partial^{\mu} U^{\dagger})^2 + \cdots$$
other 4-deriv. terms

expanded out:

$$\mathcal{L}_{\pi} = rac{1}{2} (\partial_{\mu} \pi_{a})^{2} + \cdots$$
 multiple- $\pi$  interactions  $(\pi \partial_{\mu} \pi)^{2}$ , etc.

Look familiar? it should! same setup as triplet of fields in  $L_{\Sigma}$ , but with  $v \rightarrow f_{\pi}$ . Setup is the same because the symmetry (& symmetry breaking) is the same

but remember: our goal is to have a setup where triplet PLUS h are ALL NGBs.. needs more work

First, some more observations of  $L_{\pi}$  & QCD:

- $\bullet$  number of  $\pi_a$  is set by the amount of symmetry broken
- the transformation properties of  $\pi_{\rm a}$  under unbroken symmetry (SU(2)V) also set by pattern of symmetry breaking
- $\bullet$  all interactions of  $\pi_{\rm a}$  involve  $\partial_{\mu}$

more observations of  $L_{\pi}$  & QCD:

• there is more to QCD than just  $\pi_a$ ...

There are other bound states of quarks = resonances like  $\rho$ ,  $a_1$ ,  $\omega$ . These resonances have various JPC, & interact strongly with the  $\pi_a$ .

$$M_{\rho} = 770 \text{ MeV}, \ J^{PC} = 1^{--}$$

$$M_{\omega} = 782 \text{ MeV}, \ J^{PC} = 1^{--}$$

$$M_{\alpha_{1}} = 1230 \text{ MeV}, \ J^{PC} = 1^{++}$$

$$M_{\eta} = 539 \text{ MeV}, \ J^{PC} = 0^{-+} \dots$$

$$M_{\eta} = 539 \text{ MeV}, \ J^{PC} = 0^{-+} \dots$$

They are not contained in  $L_{\pi}$ .. no first-principles way to include them, instead must use phenomenological models

adding electromagnetism:

 U(1)<sub>em</sub> is part of the SU(2)<sub>V</sub> that remains unbroken (LH, RH quarks have the same EM charge). What if we turn on this gauge interaction?

$$\partial_{\mu}U \to D_{\mu}U, \ D_{\mu}U = \partial_{\mu}U + ieA_{\mu}\hat{Q}U \qquad \hat{Q} = \begin{pmatrix} \frac{2}{3} & \\ & -\frac{1}{3} \end{pmatrix}$$

we get new interactions of pions and photons, some of which have no derivatives

loops of photons generate V( $\pi$ )

Above is just an estimate... loops of strongly coupled particles involved. For more rigorous calculation, see: Contino 1005.4269 + ref. therein

With full calculation, can show V( $\pi$ ) has a min at  $\pi = 0$ 

Π

π<sup>+</sup>, π<sup>-</sup> get mass, π<sup>0</sup>, γ stay massless

is there a  $m_\pi$  "hierarchy problem": unnatural for  $m_\pi \ll \Lambda$  ?

#### NO...we can't take $\Lambda$ arbitrarily high

#### above a certain scale, $\pi$ description no longer makes sense, the $\pi$ falls apart into its quark constituents
<u>thought experiment</u>: what if  $\pi$  interacted with fields other than the photon (some fermions, other gauge interactions, etc.)?

these other interactions would also affect V( $\pi$ ). Shape of V( $\pi$ ) no longer set...

What if V( $\pi$ ) developed a non-trivial minima?

then  $\langle \pi \rangle \neq 0$  breaks U(1)<sub>em</sub>

$$e^2 A^{\mu} A_{\mu} \pi^+ \pi^- \rightarrow e^2 v_{\pi}^2 A^{\mu} A_{\mu}$$
 photon gets a mass  
scale of the breaking is  $v_{\pi} < f_{\pi}$ 

#### clearly this is not a situation we want for QCD!

then  $\langle \pi \rangle \neq 0$  breaks U(1)<sub>em</sub>

$$e^2 A^{\mu} A_{\mu} \pi^+ \pi^- \rightarrow e^2 v_{\pi}^2 A^{\mu} A_{\mu}$$
 photon gets a mass  
scale of the breaking is  $v_{\pi} < f_{\pi}$ 

#### clearly this is not a situation we want for QCD!

BUT: shows that NGB interactions lead to a potential, and can lead to breaking of symmetries the strong dynamics respected. New scale  $v_{\pi}$  develops

based on our QCD analogy, we have a recipe for a Goldstone Higgs scenario:

- assume some strong dynamics at a high scale **f**. EWS should remain unbroken:  $\mathbf{G} \rightarrow \mathbf{H} \supset SU(2)_{w} \otimes U(1)_{Y}$
- that dynamics generates a bunch of Goldstone bosons, including the Higgs (4-plet of particles), as a doublet.
- interactions exterior to strong dynamics lead to V(h). Choose interactions such that V(h)<sub>min</sub> is at  $h \neq 0$ . Instead h<sub>min</sub> = **v** 
  - Higgs is a composite particle  $\rightarrow$  no hierarchy problem
  - v < f means EWSB happens at a scale lower than the strong dynamics

based on our QCD analogy, we have a recipe for a Goldstone Higgs scenario:

#### step 1:

- assume some strong dynamics at a high scale **f**. EWS should remain unbroken:  $\mathbf{G} \rightarrow \mathbf{H} \supset SU(2)_w \otimes U(1)_Y$
- that dynamics generates a bunch of Goldstone bosons, including the Higgs (4-plet of particles), as a doublet.
- interactions exterior to strong dynamics lead to V(h). Choose interactions such that V(h)<sub>min</sub> is at h ≠ 0. Instead h<sub>min</sub> = v
  - Higgs is a composite particle  $\rightarrow$  no hierarchy problem
  - v < f means EWSB happens at a scale lower than the strong dynamics

based on our QCD analogy, we have a recipe for a Goldstone Higgs scenario:

#### step 1:

- that dynamics generates a bunch of Goldstone bosons, including the Higgs (4-plet of particles), as a doublet.

step 2:

 interactions exterior to strong dynamics lead to V(h). Choose interactions such that V(h)<sub>min</sub> is at h ≠ 0. Instead h<sub>min</sub> = V

- Higgs is a composite particle  $\rightarrow$  no hierarchy problem
- v < f means EWSB happens at a scale lower than the strong dynamics

# Higgs Beyond the SM and SUSY lecture #2

Adam Martin CERN/Notre Dame (<u>adam.martin@cern.ch</u>)

YETI Winter School, IPPP Durham UK, 2013

### <u>Outline</u>

#### Lecture #1

- Where are we now and where do we go from here?
- Did it have to be a Higgs?
- EFT for beyond the SM
- Composite Higgs (Higgs as a Goldstone Boson)

#### Lecture #2

- more Composite Higgs (Higgs as a Goldstone Boson)
- where & how to look at LHC

# recap from yesterday:

#### idea behind composite Higgs scenario:

assume there exists some new strong dynamics in the multi-TeV range

composite objects, including H, are formed

electroweak symmetry unbroken

m<sub>H</sub> = 0 at tree level. Potential V(h) generated by loops involving gauge/Yukawa interactions

# recap from yesterday:

pions of QCD are a well-known example of similar physics:  $SU(2)_L \otimes SU(2)_R \rightarrow SU(2)_V + 3 \text{ NGB}$  $U(1)_{em} \in SU(2)_V \text{ generates } m_{\pi} \text{ (more generally, V(}_{\pi}\text{))}$ 

pions in U: 
$$U = \mathbf{1}_{2 \times 2} \exp\left(\frac{2i\vec{\pi}}{f_{\pi}}\right)$$
,  $\mathbf{U} \to \mathbf{U}_{\mathsf{L}} \mathbf{U} \mathbf{U}^{\dagger}_{\mathsf{R}}$ 

#### CH setup will get us:

- a naturally light Higgs: no hierarchy problem since the Higgs falls apart into constituents above some scale
- Higgs couplings in the  $L_{\Sigma}(a,b,c)$  form
- separation of EW physics (W/Z/h, etc.) from the strong dynamics by f/v

based on our QCD analogy, we have a recipe for a Goldstone Higgs scenario:

- assume some strong dynamics at a high scale **f**. EWS should remain unbroken:  $\mathbf{G} \rightarrow \mathbf{H} \supset SU(2)_{w} \otimes U(1)_{Y}$
- that dynamics generates a bunch of Goldstone bosons, including the Higgs (4-plet of particles), as a doublet.
- interactions exterior to strong dynamics lead to V(h). Choose interactions such that V(h)<sub>min</sub> is at  $h \neq 0$ . Instead h<sub>min</sub> = **v** 
  - Higgs is a composite particle  $\rightarrow$  no hierarchy problem
  - v < f means EWSB happens at a scale lower than the strong dynamics

based on our QCD analogy, we have a recipe for a Goldstone Higgs scenario:

#### step 1:

- assume some strong dynamics at a high scale **f**. EWS should remain unbroken:  $\mathbf{G} \rightarrow \mathbf{H} \supset SU(2)_w \otimes U(1)_Y$
- that dynamics generates a bunch of Goldstone bosons, including the Higgs (4-plet of particles), as a doublet.
- interactions exterior to strong dynamics lead to V(h). Choose interactions such that V(h)<sub>min</sub> is at h ≠ 0. Instead h<sub>min</sub> = v
  - Higgs is a composite particle  $\rightarrow$  no hierarchy problem
  - v < f means EWSB happens at a scale lower than the strong dynamics

based on our QCD analogy, we have a recipe for a Goldstone Higgs scenario:

#### step 1:

- assume some strong dynamics at a high scale **f**. EWS should remain unbroken:  $\mathbf{G} \rightarrow \mathbf{H} \supset SU(2)_w \otimes U(1)_Y$
- that dynamics generates a bunch of Goldstone bosons, including the Higgs (4-plet of particles), as a doublet.

step 2:

 interactions exterior to strong dynamics lead to V(h). Choose interactions such that V(h)<sub>min</sub> is at h ≠ 0. Instead h<sub>min</sub> = V

- Higgs is a composite particle  $\rightarrow$  no hierarchy problem
- v < f means EWSB happens at a scale lower than the strong dynamics

step 1: the art in these models is picking the right pattern of symmetry breaking...

the (global) group left unbroken by the strong dynamics:

- must contain SU(2)  $\otimes$  U(1)...
- actually SU(2)  $\otimes$  SU(2)  $\cong$  SO(4) works better (T parameter)

step 1: the art in these models is picking the right pattern of symmetry breaking...

the (global) group left unbroken by the strong dynamics:

- must contain SU(2)  $\otimes$  U(1)...
- actually  $SU(2) \otimes SU(2) \cong SO(4)$  works better (T parameter)

starting group must be bigger than ending group: choice that works: SO(5)

 $\frac{SO(5)}{SO(4)}$  : 10 generators → 6 generators just enough! SO(4) : = 4 broken generators = 4 NGB

step 1: the art in these models is picking the right pattern of symmetry breaking...

the (global) group left unbroken by the strong dynamics:

- must contain SU(2)  $\otimes$  U(1)...
- actually  $SU(2) \otimes SU(2) \cong SO(4)$  works better (T parameter)

starting group must be bigger than ending group: choice that works: SO(5)

SO(5)  
SO(4) : <sup>10</sup> generators → 6 generators just enough!  
= 4 broken generators = 4 NGB  
assemble: 
$$\Sigma = \exp\left(\frac{2i\chi_a T^a}{f}\right) \Sigma_0$$
 broken generator  
symmetry-  
breaking 'vev'

<u>Huh?</u> use  $SU(3)/(SU(2)\otimes U(1))$  as an explicit example:

$$\Sigma_{ex} = \exp\left\{ \frac{i}{f} \begin{pmatrix} & \chi_4 - i\chi_5 \\ \chi_4 + i\chi_5 & \chi_6 + i\chi_7 \end{pmatrix} \right\} \begin{pmatrix} 0 \\ 0 \\ 1 \end{pmatrix}$$

$$\Sigma_0$$

<u>Huh?</u> use  $SU(3)/(SU(2)\otimes U(1))$  as an explicit example:

$$\Sigma_{ex} = \exp\left\{ \frac{i}{f} \left( \begin{array}{cc} & \chi_4 - i\chi_5 \\ \chi_4 + i\chi_5 & \chi_6 + i\chi_7 \end{array} \right) \right\} \left( \begin{array}{c} 0 \\ 0 \\ 1 \end{array} \right)$$

 $\Sigma_0$ 

 $SU(2) \otimes U(1)$  correspond to these (unbroken) generators

<u>Huh?</u> use  $SU(3)/(SU(2)\otimes U(1))$  as an explicit example:

$$\Sigma_{ex} = \exp\left\{ \frac{i}{f} \left( \begin{array}{c} & \chi_4 - i\chi_5 \\ \chi_4 + i\chi_5 & \chi_6 + i\chi_7 \end{array} \right) \right\} \left( \begin{array}{c} 0 \\ 0 \\ 1 \end{array} \right)$$

 $SU(2) \otimes U(1)$  correspond to these (unbroken) generators

NGB come with broken generators.

The set of 4:  $\chi_{4,5,6,7}$  form a doublet under the SU(2)<sub>w</sub>  $\otimes$  U(1)<sub>Y</sub>

<u>Huh?</u> use  $SU(3)/(SU(2)\otimes U(1))$  as an explicit example:

$$\Sigma_{ex} = \exp\left\{ \frac{i}{f} \left( \begin{array}{c} \chi_4 + i\chi_5 & \chi_6 + i\chi_7 \\ \chi_4 + i\chi_5 & \chi_6 + i\chi_7 \end{array} \right) \right\} \left( \begin{array}{c} 0\\0\\1 \\ \ddots \\ \Sigma_0 \end{array} \right)$$

 $SU(2) \otimes U(1)$  correspond to these (unbroken) generators

NGB come with broken generators.

The set of 4:  $\chi_{4,5,6,7}$  form a doublet under the SU(2)<sub>w</sub>  $\otimes$  U(1)<sub>Y</sub>

$$\mathcal{L}_{\Sigma} = \frac{f^2}{4} \operatorname{tr}(D^{\mu} \Sigma_{ex} D_{\mu} \Sigma_{ex}^{\dagger}) + \cdots \qquad \text{Contains interactions of } \chi_{4,5,6,7} \text{ with}$$

$$W/Z/\gamma \text{ and each other}$$

Now for the real thing: SO(5)/SO(4)

$$\mathcal{L}_{\Sigma} = \frac{f^2}{4} \operatorname{tr}(D^{\mu} \Sigma D_{\mu} \Sigma^T) + \cdots$$

#### after LOTS of ugly group theory & algebra

$$\mathcal{L}_{\Sigma} = \frac{(\partial_{\mu}h)^2}{2} + \frac{g^2 f^2}{4} \sin^2\left(\frac{h}{f}\right) W^+_{\mu} W^{-\mu} + \frac{g^2 f^2}{8\cos^2\theta} \sin^2\left(\frac{h}{f}\right) Z^0_{\mu} Z^{0\mu}$$

Now for the real thing: SO(5)/SO(4)

$$\mathcal{L}_{\Sigma} = \frac{f^2}{4} \operatorname{tr}(D^{\mu} \Sigma D_{\mu} \Sigma^T) + \cdots$$

after LOTS of ugly group theory & algebra

$$\mathcal{L}_{\Sigma} = \frac{(\partial_{\mu}h)^2}{2} + \frac{g^2 f^2}{4} \sin^2\left(\frac{h}{f}\right) W^+_{\mu} W^{-\mu} + \frac{g^2 f^2}{8\cos^2\theta} \sin^2\left(\frac{h}{f}\right) Z^0_{\mu} Z^{0\mu}$$

$$ASSUMING: \neq 0 \quad (have to justify later with V(h))$$

$$set h \to h +  in above, and expand$$

**define**: 
$$v = f \sin\left(\frac{\langle h \rangle}{f}\right)$$

EW scale v < scale of strong dynamics f

Keep expanding: 
$$\frac{g^2 f^2}{4} \sin^2\left(\frac{h}{f}\right) W^+_{\mu} W^{-\mu}$$

$$f^{2} \sin^{2}\left(\frac{h}{f}\right) = v^{2} + 2vh\sqrt{1-\xi} + h^{2}\left(1-2\xi\right) + \cdots$$
  
where:  $\xi = \frac{v^{2}}{f^{2}}$ 

recall our Higgs EFT: 
$$m_W^2 \left( 1 + \frac{a^2 h}{v} + \frac{b^2}{v^2} + \cdots \right)$$

 $\therefore$  in the SO(5)/SO(4) composite Higgs model

$$a = \sqrt{1 - \frac{v^2}{f^2}}$$
 ,  $b = 1 - 2\frac{v^2}{f^2}$ 

bad behavior in  $W_{L}W_{L}$  amplitudes delayed by a factor of

$$(1-a)^{-1/2} \sim \frac{f^2}{v^2}$$

 eventual strong dynamics...
 ∴ expect resonances at scale ~f in analogy with to QCD

recall: precision EW bounds a require 
$$\frac{v}{f} \lesssim 0.5$$

so strong coupling scale pushed to ~ 10 TeV (at least)

other patterns of symmetry breaking would have different values for a,b,c, as well as more states

ex.) SO(6)/SO(5) has 5 NGBs, many other  $4 \in H + 1$  extra scalar  $\eta$  possibilities

### Higgs potential

#### How do we get $\langle h \rangle \neq 0$ in the first place?

right now our  $h_i$  interact with gauge fields, but we know from QCD experience that V(h) generated from these interactions alone has a minimum at h = 0

Solution: Yukawa couplings

even forgetting V(h), our theory was incomplete, because it **did not explain how fermion masses arise** 

we can write  $y f Q_L \Sigma u_R^* + h.c.$ 

but why does such a term exist? for gauge bosons, gauge invariant demanded W, Z talk to h. No such reason for the fermion mass term

### Higgs potential

Also: If we imagine  $\Sigma$  is a bound state of more fundamental fermions (the things that the composite Higgs is made of), analogous to QCD pion =  $\langle q\gamma_5 q \rangle$ 

$$y f Q_L \Sigma u_R^* \to y \frac{(Q_L u_R^*)(\psi\psi)}{\Lambda^2}$$

previous term is dimension-6, suppressed by some scale

need  $\Lambda$  low to make fermion masses big enough  $(m_t!)$ , but low  $\Lambda$  would cause large flavor problems

i.e.) 
$$\frac{(Q_L d_R^*)^2}{\Lambda^2}$$

leads to large  $K^0 - \overline{K}^0$ , B<sup>0</sup>- $\overline{B}^0$  mixing, etc.

So, try a different approach: 'partial compositeness'

- new strong dynamics makes mesons (including the h), so it can make 'baryons' = composite fermions too
- composite baryons are massive even without EWSB, just as proton would have mass even without quark masses.
- proton interacts strongly with QCD pion ... composite fermions will interact strongly with composite higgs.

- new strong dynamics makes mesons (including the h), so it can make 'baryons' = composite fermions too
- composite baryons are massive even without EWSB, just as proton would have mass even without quark masses.
- proton interacts strongly with QCD pion ... composite fermions will interact strongly with composite higgs.
- by mixing the SM fermions with the composite fermions, the SM fermions can acquire mass

- new strong dynamics makes mesons (including the h), so it can make 'baryons' = composite fermions too
- composite baryons are massive even without EWSB, just as proton would have mass even without quark masses.
- proton interacts strongly with QCD pion ... composite fermions will interact strongly with composite higgs.
- by mixing the SM fermions with the composite fermions, the SM fermions can acquire mass
- the price we pay for massive SM fermions is new states, the composite fermions. New states -> new LHC signals

#### in practice (schematically)

blue terms: come from strong sector & therefore obey same SO(5) symmetry

there are several choices for what representations composite fermions sit in (4, 5, 10, etc.), leading to slightly different structure of the interactions

Note:  $Q_L$ ,  $Q_R$ , etc. must be colored particles

Undo the mixing

 $\mathcal{L}_F = \Delta_L Q_L \mathcal{Q}_R + \Delta_R t_R \mathcal{T}_L + \mathcal{M}_Q \mathcal{Q}_L \mathcal{Q}_R + M_T \mathcal{T}_L \mathcal{T}_R + Y_T \mathcal{Q}_L \Sigma \mathcal{T}_R + h.c.$ 

 $\begin{pmatrix} \mathcal{Q}_H \\ q_L \end{pmatrix} = \begin{pmatrix} \Delta_L & \mathcal{M}_Q \\ 0 & 0 \end{pmatrix} \begin{pmatrix} Q_L \\ \mathcal{Q}_L \end{pmatrix} + \text{similar for } \mathbf{t}_{\mathsf{R}} \mathsf{T}_{\mathsf{L},\mathsf{R}}$ 

$$Q_L = \cos(\phi_L) Q_H + \sin(\phi_L) q_L$$
$$Q_L = -\sin(\phi_L) Q_H + \cos(\phi_L) q_L$$

+ similar for  $t_R T_{L,R}$ 

\*depends on representation of  $Q_L$ ,  $Q_R$ , etc.

yields  $(q_L h t_R^*) Y_T \sin(\phi_L) \sin(\phi_R)$ SM fermions get mass by mixing with composites

expanding h about 
$$c = \sqrt{1 - \frac{v^2}{f^2}}$$
 vev, find c\*:

#### About that potential

within this setup, we can calculate the V(h) from loops of fermions, in same fashion as done before

#### About that potential

 $V_{min}$  at  $h \neq 0$  is possible, requires delicate balance between +ve and -ve contributions to obtain v  $\ll$  f = requires some 'tuning' of parameters

#### 1.) Higgs couplings: a, b, c

study all possible Higgs production and decay process to extract a, c intricate process, as different production mechanisms scale differently with a, c, and contribute differently to each final state

#### 1.) Higgs couplings: a, b, c

study all possible Higgs production and decay process to extract a, c intricate process, as different production mechanisms scale differently with a, c, and contribute differently to each final state

different composite Higgs models → different a, c, possibly even extra Higgs decay modes from new particles

BUT, careful: H + jj is not VBF alone, H+0j is not just gg  $\rightarrow$  H also,  $\Gamma_{\rm H}$  knows about all  $c_{\rm i}$ 

#### company of the contract of the

[from J. Galloway]

coupling b is trickier.. requires studying multi-Higgs production in detail

low cross section and b must be disentangled from other hh production diagrams

see ex.) [Dolan, Englert, Spannowsky 1206.5001,1210.8166]

W<sup>+</sup>W<sup>-</sup>h<sup>3</sup> signal .. from further expansion of f sin<sup>2</sup>(h/f)

doesn't exist at tree level in the SM

coupling b is trickier.. requires studying multi-Higgs production in detail

low cross section and b must be disentangled from other hh production diagrams

high-luminosity needed!

see ex.) [Dolan, Englert, Spannowsky 1206.5001,1210.8166]

W<sup>+</sup>W<sup>-</sup>h<sup>3</sup> signal .. from further expansion of f sin<sup>2</sup>(h/f)

doesn't exist at tree level in the SM

2.) production of new particles

we've seen that composite Higgs models generically have new vector (spin-1: W', Z',W'') and fermion (T', B') resonances

- interactions of Higgs with W/Z set by choice of symmetry breaking... much more model dependence for resonances & their interactions
- additional complication: we know the theory is strongly coupled.. no obvious 'best' way to proceed.

One idea: rescale properties of QCD resonances

$$\rho \to W'$$
 ,  $M_{W'} = \sqrt{\frac{3}{N_C}} \frac{f}{f_\pi} M_\rho~$  ~ 4 TeV for f = 2 v

not very quantitative

# Extra dimensional models on a slide

One way to model the strong dynamics is with an extra dimension

but not fundamental, just a model

#### <u>spin-1 resonances:</u>

slight mixing between W', Z' and W, Z, means new resonances produced most easily in *ŝ*-channel

may look like usual W', Z'

BUT: W',Z' couple strongest to other strong-sector states, like the longitudinal W, Z & h (even t). Big couplings mean  $\Gamma_{W'}$ , etc. can be big.

usual W', Z' LHC searches assume zero (or very small) W'WZ interactions... these **need to be reinterpreted** for particles w/ strong interactions with W, Z, etc.

cleanest signal for W/Z decay products is the fully leptonic mode: W'  $\rightarrow$  WZ  $\rightarrow$  3  $\ell$  + v

semi-leptonic modes ( $\ell \ \ell \ + jj$ ,  $\ell \nu + jj$ ) look swamped by background (W/Z + jets) ...

but we can use the fact that W, Z from a ~few TeV W' will be **highly boosted** 

angular sepn. of W→jj ~ 2 m<sub>W</sub>/p<sub>T</sub> ~ 0.3 for p<sub>T</sub> ~ 500 GeV .. both decay products fall into the same 'jet'

jet 'substructure' will be an essential tool for uncovering such signals [Butterworth et al '08, Kaplan et al '08, ...]

tutorial session at work!

#### <u>fermionic resonances = new heavy fermions</u>

exactly what states are present & their masses depends on details of the composite fermions (masses M, representations)

simple example, to show some general features:  $t_R$  mixing with composites T,  $T^c \in (3,1)_{2/3}$ 

$$y_t Q_3 H t^c + M T T^c + \delta T t^c + h.c.$$

$$(t T) \begin{pmatrix} m & 0 \\ \delta & M \end{pmatrix} \begin{pmatrix} t^c \\ T^c \end{pmatrix}$$

$$\mathcal{L} \supset \frac{m_t \cos^2 \theta_l}{v} h \bar{T}_D(\tan \theta_r P_L + \tan \theta_l P_R) t_D$$

$$+ \frac{g_2 \sin \theta_l \cos \theta_l}{2 \cos \theta_W} Z_\mu (\bar{T}_D \gamma^\mu P_L t_D + \bar{t}_D \gamma^\mu P_L T_D)$$

$$+ \frac{g_2 \sin \theta_l}{\sqrt{2}} (W_\mu^+ \bar{T}_D \gamma^\mu P_L b_D + W_\mu^- \bar{b}_D \gamma^\mu P_L T_D)$$

Branching ratio, up to small corrections, set by Goldstone equivalence:

Branching ratio, up to small corrections, set by Goldstone equivalence:

 $T \longrightarrow t$ 

 $\sim 25\%$ 

T decay modes

 $\sim 50\%$ 

Branching ratio, up to small corrections, set by Goldstone equivalence:

T decay modes

 $\sim 25\%$ 

 $\sim 25\%$ 

 $\sim 50\%$ 

 $\boldsymbol{b}$ 

#### in large mass limit, only parameter is M<sub>T</sub>

Branching ratio, up to small corrections, set by Goldstone equivalence:

 $\sim 25\%$ 

T decay modes

 $\sim 25\%$ 

in large mass limit, only parameter is M⊤ extra 'chiral' quarks (4th generation) only have this decay mode

both pair-production (T  $\overline{T}$ ) and single production possible. Pair production dominates for  $M_T \leq 1 \text{ TeV}$ 

- fairly large cross section
- lots of W,Z,h, b in the final state  $T\overline{T} \rightarrow tZ^{0}\overline{b}W^{-} + c.c.$   $T\overline{T} \rightarrow tZ^{0}\overline{b}W^{\mp}\ell^{\mp}\mathfrak{G}+(W)$   $(W) = \overline{\ell\nu} \text{ or } bjj\ell^{+}\ell^{-}b + (W)$   $(W) = \ell\nu \text{ or } tZ^{0}\overline{t}h^{0} + c.c.$   $\rightarrow bjj\ell^{+}\ell^{-}b\ell\nu bb$

existing limits on T', B':

assume 100% BR into one mode:  $T \rightarrow W b$  (4th gen),  $T \rightarrow t Z$ 

so, limits need to be reinterpreted. Mixed modes likely to yield stronger constraints.

substructure could be useful for identifying hadronic W/Z

more exotic possibilities:

In some scenarios, Q<sub>3L</sub> doublet is extended & includes higher charge states: X<sub>5/3</sub>, or X<sub>7/6</sub>

cascade decays of  $X \rightarrow t W \rightarrow W b$ gives like-sign dileptons

low SM background

#### LHC signals: summary

• the era of precision Higgs: composite-ness of the Higgs is encoded in deviations of couplings from their SM values

mass scale of new particles ~f is constrained via Higgs coupling measurements. More SM-like couplings → smaller v/f → heavier new states

• direct production of new particles:

both spin-1 and fermionic resonances have large couplings to W/Z/h/t: W/Z/h/t-rich final states

W'/Z'/T' have different properties than LHC searches usually assume -- care required in interpreting limits

### **Conclusions**:

- immediate LHC focus: how SM Higgs-like is X(125)?
   L<sub>Σ</sub> EFT is a good framework to use, look for deviations a,b,c≠1
   a,b,c≠1 indicate strong coupling enters at some scale
- <u>Composite Higgs</u>: Higgs as a Goldstone boson. UV setup that gives light Higgs + a,b,c≠1

gauge and Yukawa interactions generate nontrivial V(h) and lead to EWSB. tuning of different contributions to get  $v \ll f$ 

other composites (spin-1, fermions) in spectra, possible targets for LHC searches.

different than 'generic' W'Z'/T': large couplings to W/Z/h/t
