# Determination of the basic Higgs-boson couplings from combined analysis of WW/ZZ decays at LHC, ILC and Photon Collider

A.F. Żarnecki, Warsaw University

with P. Nieżurawski and M. Krawczyk NŻK

LHC / LC Study Group meeting SLAC, March 23, 2005

#### <u>Outline</u>

- Higgs couplings in 2HDM (II)
- Higgs production at LHC, ILC, and PLC
- Combined analysis
- 2HDM (II) with CP violation

# CP conserving 2HDM (II)

#### Higgs boson couplings

Scalar Higgs bosons h and H with basic couplings (relative to SM):

$$\chi_x = g_{\mathcal{H}xx}/g_{\mathcal{H}xx}^{SM} \quad \mathcal{H} = h, H, A$$

	h	H	A
$\chi_u$	$rac{\cos lpha}{\sin eta}$	$rac{\sinlpha}{\sineta}$	$-i\;\gamma_5\;rac{1}{ aneta}$
$\chi_d$	$-rac{\sinlpha}{\coseta}$	$rac{COS lpha}{COS eta}$	$-i\;\gamma_{5}$ $ aneta$
$\chi_V$	$\sin(\beta-\alpha)$	$\cos(\beta - \alpha)$	0

For charged Higgs boson couplings (loop contribution to  $\Gamma_{\gamma\gamma}$  ) we set

$$M_{H^{\pm}} = 800 \; GeV \qquad \mu = 0$$

Higgs couplings are related by "patter relation"

$$(\chi_V - \chi_d)(\chi_u - \chi_V) + \chi_V^2 = 1$$

I. F. Ginzburg, M. Krawczyk and P. Osland, hep-ph/0101331

Instead of angles  $\alpha$  and  $\beta$  use couplings  $\chi_V$  and  $\chi_u$  to parametrize cross sections

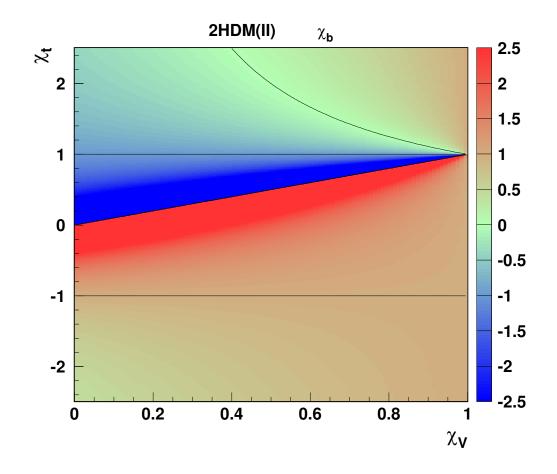

$$0 \leq \chi_V \leq 1$$

If we neglect H decays to h and A (small) cross sections and BRs calculated for H are also valid for h

# 2HDM (II)

Basic relative coupling to down-type fermions as a function of vector boson and top (up-type fermions) couplings:

$$\chi_d = \chi_V + \frac{1 - \chi_V^2}{\chi_V - \chi_u}$$

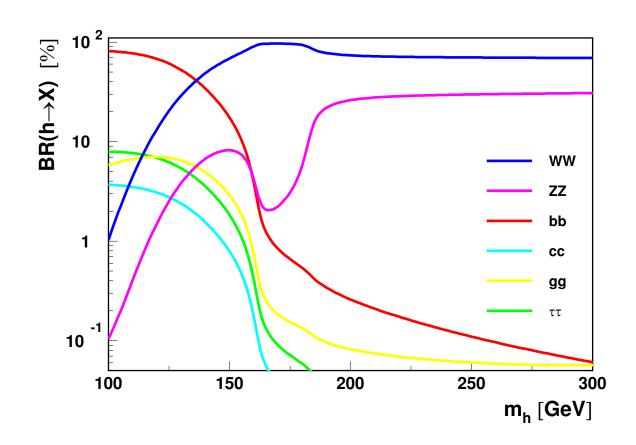

# 2HDM (II)

Higgs boson production at LHC, ILC and PLC, for Higgs boson mass between 200 and 350 GeV

For SM-like scenarios ( $\chi \sim 1$ ) Higgs boson decays to WW and ZZ dominate.

#### SM branching ratios

# LHC

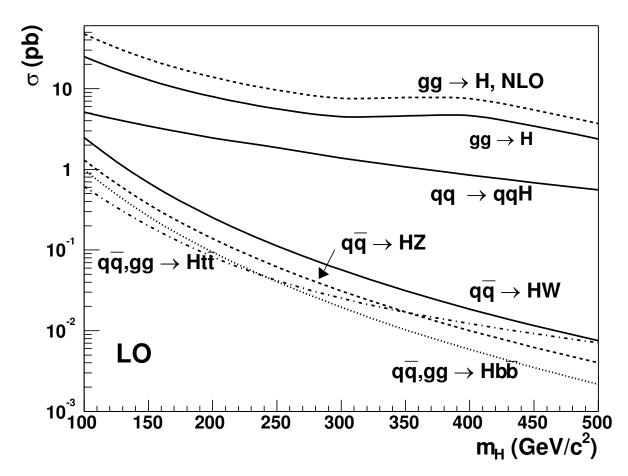

In the considered mass range Higgs boson production at LHC is dominated by the gluon fusion process.

 $\Gamma_{hgg}$  is dominated by the top loop contribution  $\Rightarrow$ 

$$\sigma(gg \to h) \sim \chi_t^2$$

WW fusion process contributes to about 15% of cross section

$$\sigma(qq \to qqh) \sim \chi_V^2$$

SM Higgs boson production at LHC

Measurement of the production cross section times branching ratio

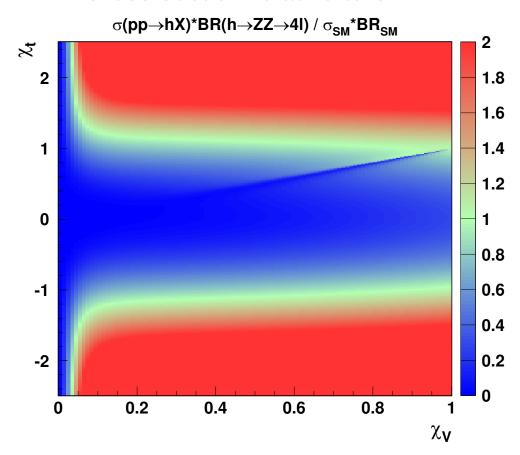

$$\sigma(pp \to hX) \cdot BR(h \to ZZ \to 4l)$$

"golden channel"

will constrain mainly the  $|\chi_u|$  value, provided  $\chi_V$  is not too small.

We use results of C.P.Buszello, I.Fleck, P.Marquard, J.J. van der Bij, Eur. Phys. J. C32(2004)209 hep-ph/0212396

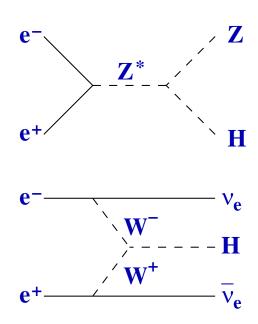

Precision  $\sim$  15% expected

# ILC

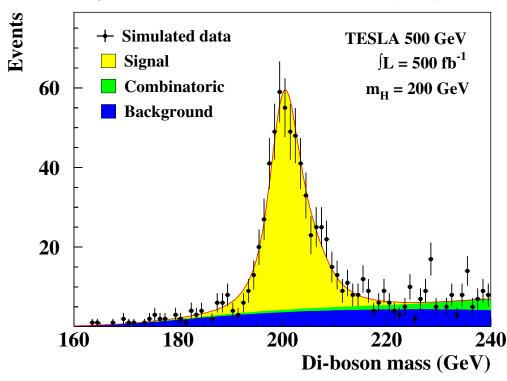

For Higgs boson production at TESLA  $(\sqrt{s} = 500 \; GeV, 500 \; \text{fb}^{-1})$ 

two processes are considered

Production is sensitive only to  $\chi_V$ 

#### Expected mass distribution (SM)

N.Meyer, Eur. Phys. J. C35 (2004) 171 hep-ph/0308142

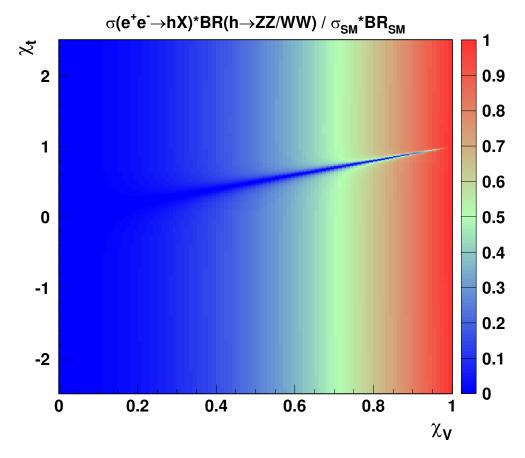

Measurement of the production cross section times branching ratio

$$\sigma(e^+e^- \to hX) \cdot BR(h \to WW/ZZ)$$

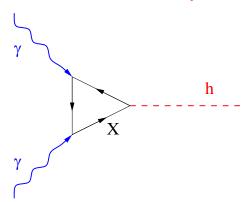

is possible with precision  $\sim 4-7\%$  (SM-like scenario, 500 fb<sup>-1</sup>)

This will constrain the  $\chi_V$  value

# PLC

Cross section for the Higgs boson production at the Photon Collider is proportional to the two-photon width

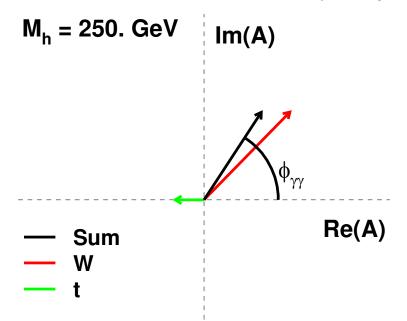

$$\Gamma(h \to \gamma \gamma) = \frac{G_F \alpha^2 M_h^3}{128\sqrt{2} \pi^3} \cdot |\mathcal{A}|^2$$

where:

$$\mathcal{A} = A_W(M_W) + \sum_f N_c Q_f^2 A_f(M_f) + \dots$$
two-photon amplitude

In SM, dominant contributions to two-photon amplitude  $\mathcal{A}$  are due to  $W^{\pm}$  and top loops.

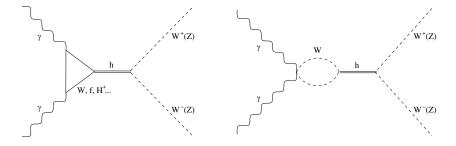

Phases of  $W^{\pm}$  and top contributions differ Phase of top distribution changes with  $\Phi_{HA}$ !

 $\Rightarrow$  Both  $\Gamma_{\gamma\gamma}$  and the phase of the amplitude  $\phi_{\gamma\gamma}$  depend on  $\chi_V$  and  $\chi_t$ 

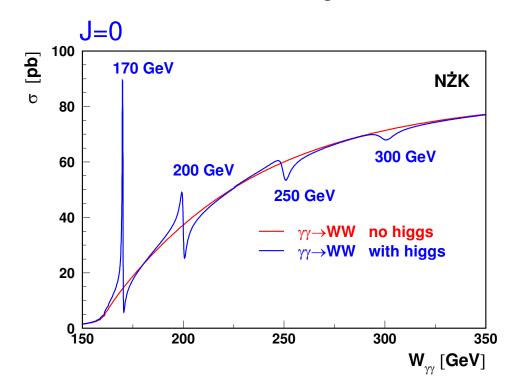

For resonant  $\gamma \gamma \rightarrow h \rightarrow W^+W^-$  signal

there is a large non-resonant bg.

Large interference effects are expected in the considered mass range

Interference is sensitive to the phase of the two-gamma amplitude

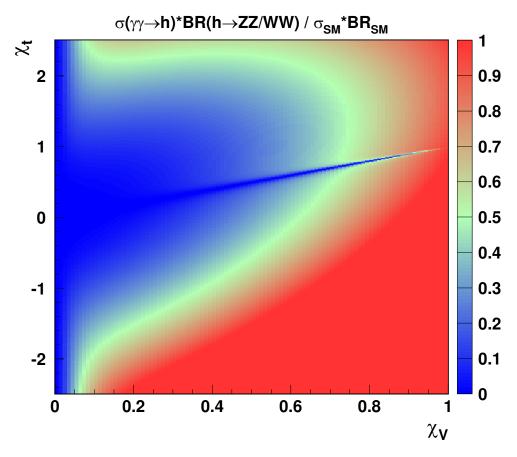

# PLC

Measurement of the production cross section times branching ratio

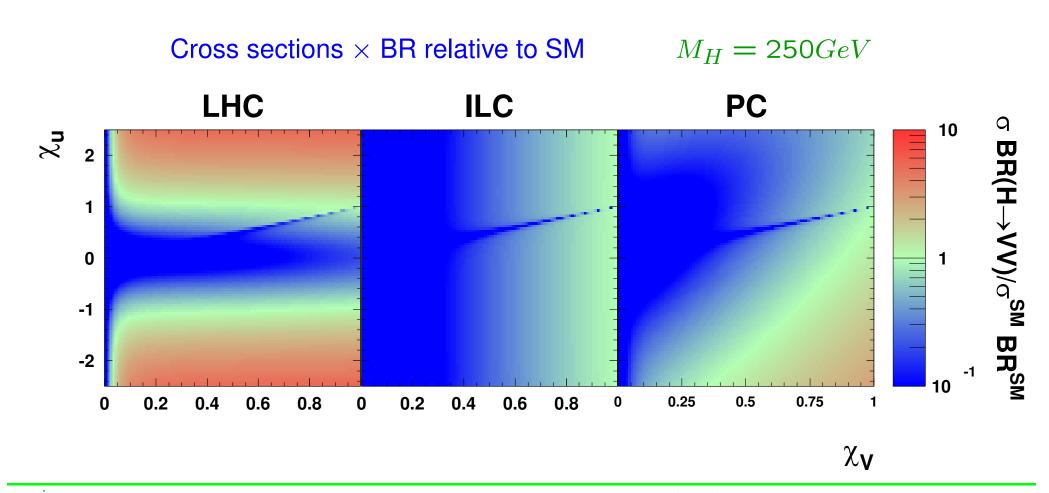

$$\sigma(\gamma\gamma \to h) \cdot BR(h \to WW/ZZ)$$

is possible with precision  $\sim 4-9\%$ 

 $\phi_{\gamma\gamma}$  can be measured with precision 40 - 120 mrad JHEP 0211 (2002) 034 [hep-ph/0207294]

Measurements at LHC, ILC and Photon Collider are complementary, being sensitive to different combinations of Higgs-boson couplings

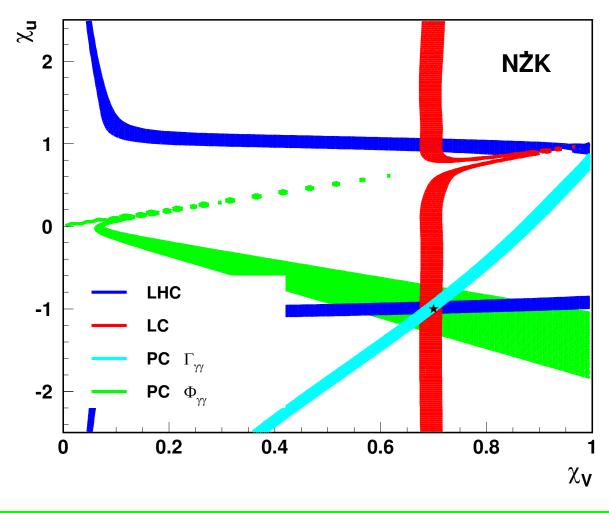

Allowed coupling values (1  $\sigma$ ) from cross section measurements at LHC, ILC and PC, and the phase measurement at PC.

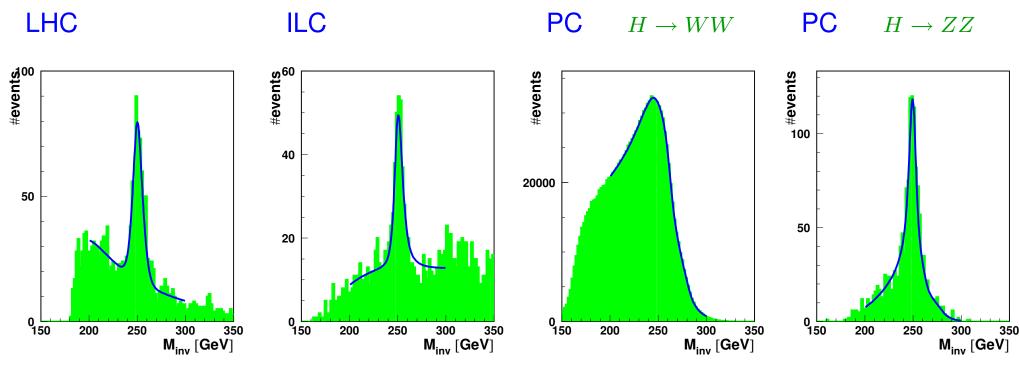

Consistency of all these measurements verifies the coupling structure of the model

statistical errors only

Combined fit to the expected invariant mass distributions:

9 parameter fit:  $\bullet \chi_V \bullet \chi_u \bullet M_H$ 

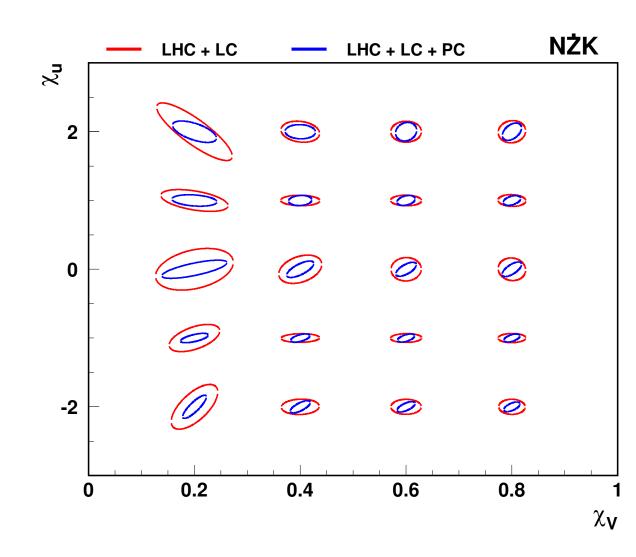

+ 6 normalization and  $\gamma\gamma$ -spectra shape parameters (systematic uncertainties)

Simultaneous fit to LHC, ILC and PC ( $W^+W^-$  and ZZ) invariant mass distributions

$$1\sigma$$
 (stat.+sys.) contours

Comparison of error contours for combined analysis without and with weak PC

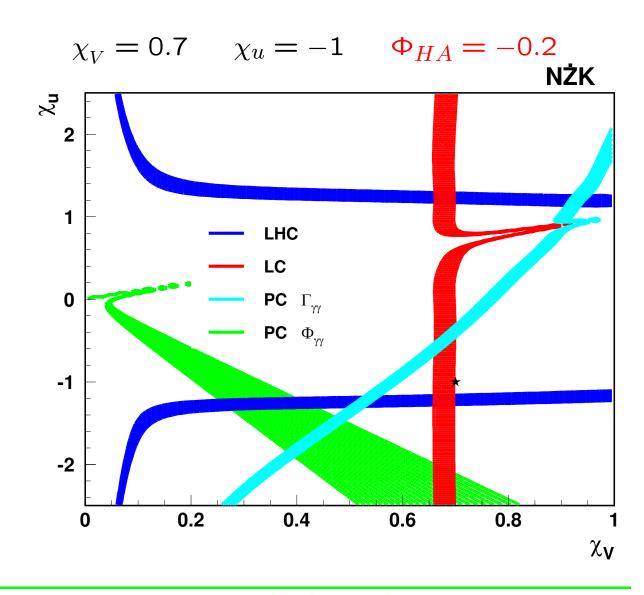

H couplings to vector bosons  $(\chi_V)$  and up fermions  $(\chi_u)$  for  $M_H=250~{\rm GeV}$ 

Allowed coupling values from cross section measurements at LHC, ILC and PC, and the phase measurement at PC.

Measurements compared assuming CP-conserving 2HDM(II) not consistent ⇒ "new physics":

- different coupling structure (eg. CP violation)
- existence of new heavy particles contributing to  $\Gamma_{gg}$  and  $\Gamma_{\gamma\gamma}$

## 2HDM (II) with CP violation

#### H-A mixing

Mass eigenstates of the neutral Higgs-bosons  $h_1$ ,  $h_2$  and  $h_3$  do not need to match CP eigenstates h, H and A.

We consider weak CP violation through a small mixing between H and A states:

$$\begin{array}{lll} \chi_X^{h_1} & \approx & \chi_X^h \\ \chi_X^{h_2} & \approx & \chi_X^H \cdot \cos \Phi_{HA} \, + \, \chi_X^A \cdot \sin \Phi_{HA} \\ \chi_X^{h_3} & \approx & \chi_X^A \cdot \cos \Phi_{HA} \, - \, \chi_X^H \cdot \sin \Phi_{HA} \end{array}$$

 $\Rightarrow$  additional model parameter: **CP-violating mixing phase**  $\Phi_{HA}$ 

⇒ see our paper JHEP 0502:041,2005 [hep-ph/0403138]

In general case

combined analysis of LHC, Linear Collider and Photon Collider data is needed

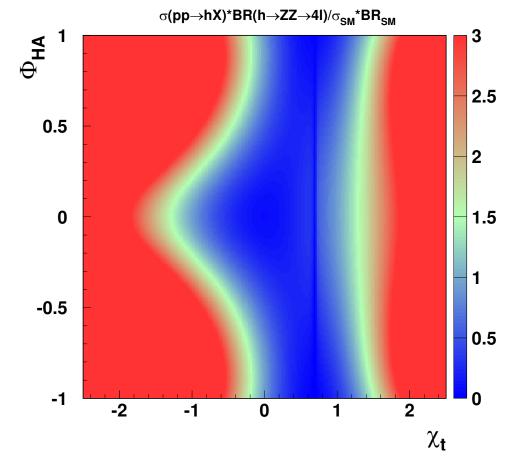

We consider  $h_2$  production and decays, for  $|\Phi_{HA}| \ll 1$  (weak CP violaion)

Measurement of the production cross section times branching ratio

$$\sigma(pp o hX) \cdot BR(h o ZZ o 4l)$$
 not sensitive to  $\chi_V$  constrains mainly  $|\chi_u|$  value

Limited sensitivity to  $\Phi_{HA}$  for  $\Phi_{HA} pprox \mathbf{0}$ 

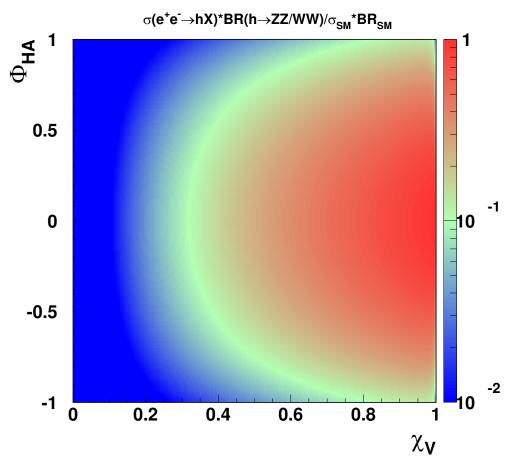

Measurement of the production cross section times branching ratio

$$\sigma(e^+e^- o hX) \cdot BR(h o WW/ZZ)$$
 not sensitive to  $\chi_t$  constrains mainly  $\chi_V$  value

Even smaller sensitivity to  $\Phi_{HA}$  for  $\Phi_{HA} \approx 0$ 

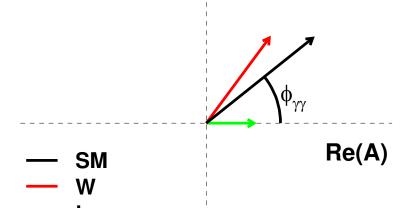

# PLC

Contributions from  $W^{\pm}$  and top loops to the two-photon amplitude:

#### CP-conserving 2HDM (II)

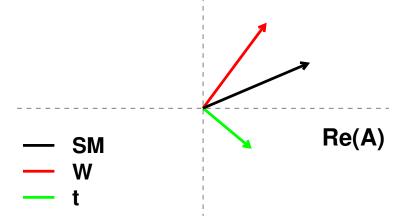

$$\chi_V = 0.7, \chi_t = -1$$

#### 2HDM (II) with weak CP violation

$$\chi_V = 0.7, \chi_t = -1, \Phi_{HA} = -0.2$$

$$M_h = 300. \text{ GeV}$$
  $Im(A)$ 

Significant change both in  $\Gamma_{\gamma\gamma}$  and in  $\phi_{\gamma\gamma}$ 

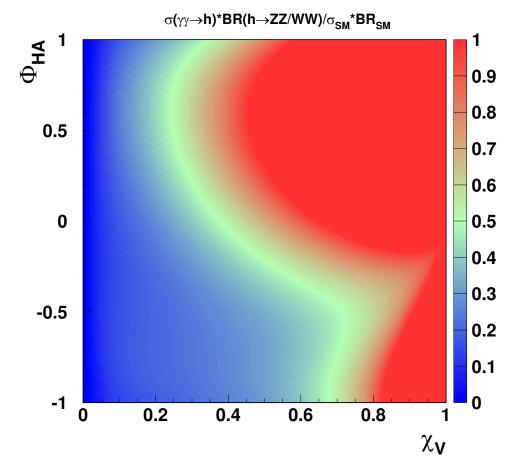

Measurement of the production cross section times branching ratio

$$\sigma(\gamma\gamma \to h) \cdot BR(h \to WW/ZZ)$$

sensitive to both  $\chi_V$  and  $\chi_t$ 

also very sensitive to  $\Phi_{HA}$ 

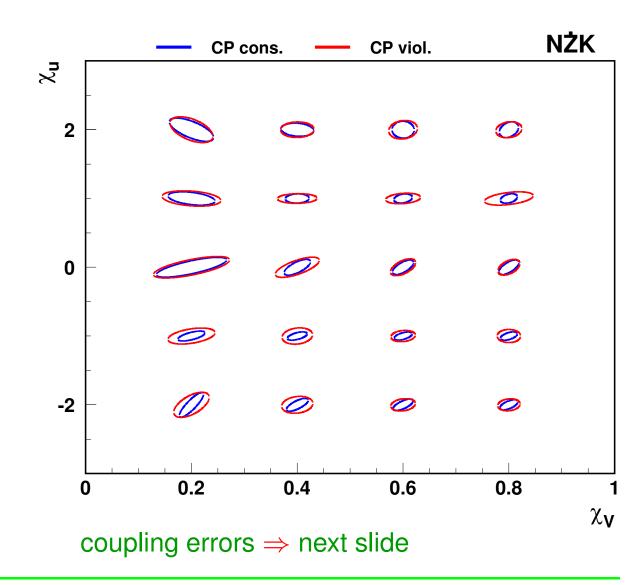

Simultaneous fit to LHC, ILC and PC ( $W^+W^-$  and ZZ) invariant mass distributions

$$1\sigma$$
 (stat.+sys.) contours

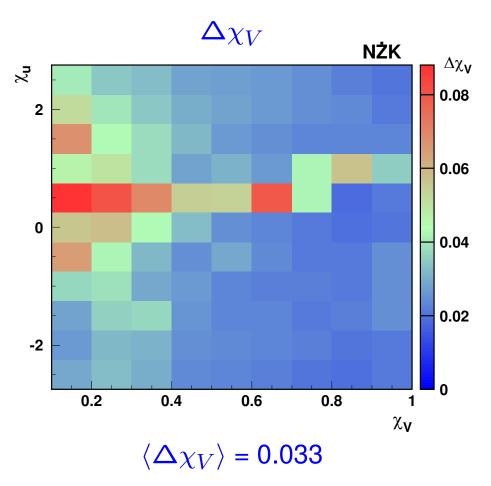

Comparison of error contours for model without and with weak CP violation

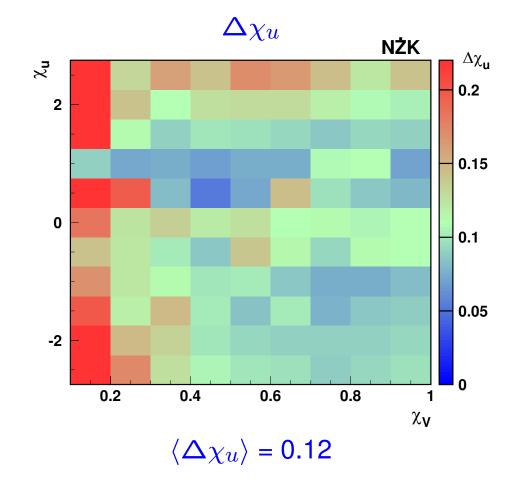

H couplings to vector bosons  $(\chi_V)$  and up fermions  $(\chi_u)$  for  $M_H=250~{\rm GeV}$ 

### Coupling errors

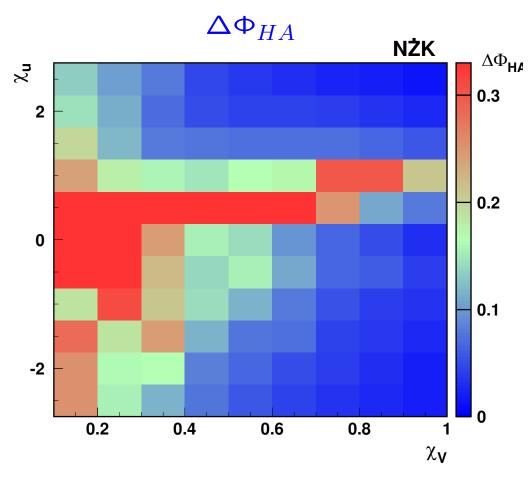

Estimated total errors on Higgs boson couplings for  $M_H$ =250 GeV

#### $\Phi_{HA}$ error

Estimated total errors on H-A mixing angle, for  $M_H$ =250 GeV

For a wide range of couplings  $\Delta \Phi_{HA} \leq 100 \text{ mrad}$ 

Determination of  $\Phi_{HA}$  not possible without Photon Collider data

$$\langle \Delta \Phi_{HA} \rangle$$
 = 150 mrad

# Summary

Heavy Higgs boson production and decays to WW/ZZ studied for masses between 200 and 350 GeV.

2HDM(II) considered, without and with (weak) CP violation

Measurements at LHC, ILC and Photon Collider are complementary, being sensitive to different combinations of Higgs-boson couplings.

Only the combined analysis of LHC, ILC and PC measurements allows for the determination of the CP-violating H - A mixing angle  $\Phi_{HA}$ .

In most of the considered parameter space  $\Phi_{HA}$  measured to better than 100 mrad.

# Systematic uncertainties

#### LHC ⊕ ILC ⊕ PC analysis

#### Parameter:

- Higgs boson mass
- ullet  $\gamma\gamma$  luminosity
- $\gamma\gamma$  spectra shape parameters
- background normalization for  $e^+e^-$
- signal normalization for pp
- ullet background normalization for pp

#### Assumed uncertainty:

- ⇒ unconstrained
- ⇒ unconstrained
- ⇒ 5% uncertainty
- ⇒ 5% uncertainty
- → 10% uncertainty
- → 10% uncertainty
